Module 2: Python Foundations for Data Science

Module 2 is where we move from *thinking like a data scientist* to *building like a data scientist*.

This module focuses on the core programming tools that allow us to collect, manipulate, store, and retrieve data using Python.

Below are the key big ideas that tie everything together.

1 Python Is About Data Structures

At its core, Python gives us structured ways to store and manipulate data.

Core Data Types

- Integers, floats, strings, booleans
- Lists and tuples (ordered collections)
- Dictionaries (key-value pairs)
- Sets (unique unordered collections)

Why This Matters

Data science is about working with structured information.

Before we analyze data, we must understand how Python represents data.

You are learning:

- How data is stored
 - How to access it
 - How to modify it
 - When immutability matters
-

2 Strings and Text Processing Matter

A huge portion of real-world data is text.

Strings in Python are sequences of characters and support:

- Indexing and slicing
String operations
- Concatenation
- Replication
- String methods like `.upper()`, `.replace()`, `.find()`

Why This Matters

APIs, web scraping, file input/output, and raw datasets often start as text.

If you can manipulate strings confidently, you can clean and transform messy data.

3 Files Are Data Pipelines

Data scientists constantly read and write data.

You learned how to:

Read Files

- Use `open()` in read mode
Reading files with Open
- Use `.read()`, `.readline()`, `.readlines()`
- Use `with` statements (best practice)

Write Files

- Use `open()` in write mode
Writing files with Open
- Use `.write()`
- Append to files
- Copy files programmatically

Why This Matters

Reading files is how data enters your system.

Writing files is how results leave your system.

This is the foundation of reproducible workflows.

4 Data Comes in Many Formats

Real-world data is messy and diverse.

You explored:

- CSV files
- JSON files
- XML files

Using libraries like:

- Pandas
- json
- xml.etree

Why This Matters

Data scientists rarely control the format of incoming data.

You must be adaptable.

Understanding formats = understanding data ingestion.

5 Pandas Turns Raw Data into DataFrames

Pandas is one of the most important libraries in data science.

You learned how to:

- Load CSV files
- Inspect unique values
 - Working with and saving data
- Filter rows using Boolean conditions

- Save results with `.to_csv()`

Big Idea:

A DataFrame is a programmable spreadsheet.

Once data is in a DataFrame:

- You can filter
- Aggregate
- Transform
- Export

This is where data science begins to feel powerful.

6 NumPy Makes Computation Fast and Scalable

NumPy arrays are:

- Fixed size
 - Typed
 - Optimized for speed
- Two dimensional NumPy

You learned:

- 1D arrays
- 2D arrays
- Indexing and slicing
- Vectorized operations
- Matrix multiplication

Big Idea:

Vectorization replaces loops.

Instead of iterating through values manually, NumPy performs operations across entire arrays efficiently.

This is critical for machine learning later.

7 The Internet Is a Data Source

Modern data science often pulls data from the web.

You explored:

REST APIs and HTTP requests

- Requests
- Responses
- Status codes
- GET vs POST

Python Requests Library

- Sending GET requests
- Passing parameters
- Parsing JSON responses

Web Scraping with BeautifulSoup

- Parsing HTML
- Navigating the DOM tree
- Using `find_all()`
- Extracting structured information

Big Idea:

Data is not just in files.
It lives on servers.

Knowing how to retrieve it programmatically gives you leverage.

8 Automation Is the Superpower

Putting everything together:

- Read data
- Clean strings
- Filter rows
- Transform arrays
- Write outputs

- Pull new data from APIs
- Scrape websites

All with code.

This is automation.

Data scientists do not copy and paste.
They build repeatable pipelines.

9 Everything Connects

Module 2 is not composed of random topics.

It is a workflow:

1. Understand data types
2. Store structured information
3. Read files
4. Transform data
5. Work with DataFrames
6. Use arrays for computation
7. Pull data from APIs
8. Scrape web data
9. Save results

That is the skeleton of modern data science. Once you master these fundamentals, you are no longer just running notebooks.

You are engineering data workflows.

And that is what real data scientists do.
